

SUBSYSTEM AND METHOD OF ORGANIZING MULTIPLEXED DATA

This is a continuation of application number 10/348,783 filed 23 January 2003, which is a continuation of application number 09/982,935 filed 22 October 2001, which is a continuation of application number 09/256,859 filed 24 February 1999, the contents of which are incorporated herein by reference.

BACKGROUND OF THE INVENTION

The present invention relates to a multiplexed data memory
5 system in which an external memory control unit which receives
a write command from a host unit and which memorizes the received
write command in an external memory unit under its control as
original data writes the same data as that original data in the
external memory unit operable under different external memory
10 control units as backup data. More particularly, the present
invention relates to a multiplexed data reorganizing system
capable of effectively utilizing backup data and which is also
able to efficiently reorganize the duplexing of original data
obtained after backup data was used and the backup data, and
15 relates to a subsystem for carrying out this system.

In a multiplexed data memory system in which data used in
a host unit such as a host computer is multiplexed and held by
a plurality of external memory units, e.g. original external
memory unit and sub-external memory unit, as a method of holding
20 the multiplexing of data between the original external memory unit
and the sub-external memory unit, there are generally known
technologies disclosed in Japanese Published Unexamined Patent
Application No. Hei 6-214853, Japanese Published Unexamined
Patent Application No. Hei 7-6099, Japanese Patent No. 2509460
25 and Japanese Translation of PCT Application No. Hei 8-509565.

According to the method disclosed in the above-mentioned technologies, an original external memory unit and sub-external memory unit are provided under control of different external memory control units, the original external memory control unit and the sub-external memory control unit are connected via an interface cable and a write command received at the original-side external memory control unit is issued to the sub-side external memory control unit, thereby resulting in the multiplexing of data of the original external memory unit and the sub-external memory unit being maintained.

In such multiplexed data memory system, as a method of reorganizing the multiplexing after the multiplexing is interrupted, there is known a method of copying only an update place of an original external memory unit which is interrupted in multiplexing to a sub-side external memory unit, i.e. so-called difference copy.

In this difference copy, data of the sub-side external memory unit is generally used as backup data of the original-side external memory unit. During data is duplexed, a write access and a read access are generally inhibited from a standpoint of coincidence of original data and sub-data.

SUMMARY OF THE INVENTION

Recently, although a demand of effectively utilizing backup data increases from a standpoint of increasing an efficiency of

a business, an inefficient procedure should be unavoidably made in order to reorganize the multiplexing after the access on the backup data was ended.

When backup data is temporarily used as test program data by utilizing the duplexed data memory system, for example, or when backup data of data of a certain time point is obtained from a sub-side external memory unit and saved in other memory medium, further when a trouble occurs the sub-side external memory unit and when the sub-side external memory unit is accessed in order to execute a program for restoring such trouble, if the duplexing of data should be released and the duplexing of data should be formed again, then all data of the original-side external memory unit should be copied to the sub-side external memory unit.

However, in this case, when a difference of several tracks at most occurs in the original-side and sub-side data due to the access on the sub-side external memory unit, according to the above-mentioned method of reorganizing the multiplexed data, there is then the problem that an efficiency of re-arrangement is not excellent.

Also, when a business is temporarily shifted to the sub-side system, the duplexed state of data should be released. When the business is again returned to the original-side system, the old sub-side system is provisionally set in the original-side system and the old original-side system is provisionally set in the sub-side system thereby duplexing the data. Further, the

duplexed state is released, the provisional sub-side system is returned to the original system, the provisional original-side system is returned to the subsystem and the business is resumed in the inherent original-side system. Such a complex procedure
5 should be executed.

That is, in the conventional multiplexed data memory system, the multiplexed state should be released in order to access the backup data. When the multiplexing is reorganized after the accessing was ended, an inefficient procedure requiring the
10 initialization should be executed.

A problem of the present invention is that, under circumstances in which the multiplexing of data is organized, after read and write accessing was made on data generally saved as backup data, the multiplexing of data may be reorganized
15 efficiently.

A fundamental feature of the present invention lies in that, under circumstances in which the multiplexing of data is organized, after read and write accessing was made on data generally saved as backup data, when the multiplexing of data is organized again,
20 the multiplexing may be reorganized efficiently by copying only the update places obtained by the access from the original system to the subsystem or from the subsystem to the original system.

A feature of the multiplexed data processing system according to the present invention has a function to issue an
25 original disk control unit write command to the sub-disk control

unit which controls the backup data in the multiplexed data memory system in which disk units which are under control of different disk control units have the same data.

Thus, update places of original and sub data updated during data is multiplexed are registered on the access information management table of the original disk control unit as access information. When the original disk control unit receives a duplexing resume command, it becomes possible to efficiently reorganize the duplexing by copying original data corresponding to the access place occurred in the duplexing interruption from the information of the access information management table to the backup data or copying the backup data to the original data.

Also, a feature of the multiplexed data processing system according to the present invention is that it has a function to register access places on the access information management table.

The duplexing re-arrangement in the duplexed data memory system according to the present invention and its action will be described concretely as follows.

Initially, each time the write access occurs in the backup data obtained during the duplexing is interrupted in the channel command analyzing section of the subsystem, the access place is registered on the access information management table.

Then, when the channel command analyzing section receives an access end command relative to the backup data, the channel command analyzing section reports it to the original system. The

original system reads out information from the access information management table of the subsystem, merges the read-out information to the access information of the original system and registers the merged information on the access information management table.

5 When the channel command analyzing section of the original system receives the duplexing resume command, the access information management table is checked, and a write command or a read command of data of the access place is issued to the subsystem, thereby reorganizing the duplexing.

10 The feature of the present invention will be described more in detail. The present invention is a subsystem comprising means for recognizing whether or not the access of the original side external memory control unit on the sub-side external memory unit is started or ended and means for judging which data of the
15 original-side and sub-side external memory control units should be used as original data when the duplexing of data is reorganized after the backup data was updated and wherein the original-side and sub-side external memory control units include means for recognizing the access situation of the backup data.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram showing a data processing system according to an embodiment of the present invention;

FIG. 2 is a block diagram showing inside arrangements of
25 original and sub-disk control units in FIG. 1;

FIG. 3 is a table showing a correspondence between the state contents registered on a state management table and their abbreviations;

FIG. 4A is a flowchart showing a flow of a processing executed by a sub-disk control unit until a state management table is set and an access information management table is set after the access occurred in the sub-disk unit;

FIG. 4B is an example of an access registration processing ① of FIG. 4A;

FIG. 4C is another example of an access registration processing ① of FIG. 4A;

FIG. 5A is a flowchart showing a flow of a processing executed by the sub-disk control unit until access information is reported to the original disk control unit after the access to the sub-disk unit was ended;

FIG. 5B is an example of an access information reporting processing ② of FIG. 5A;

FIG. 5C is another example of an access information reporting processing ② of FIG. 5A;

FIG. 6A is a flowchart showing a flow of a processing executed by the original disk control unit until access information of the sub-disk unit is obtained after the access end report relative to the sub-disk unit was received; and

FIG. 6B is an example of an access information registration processing ③ of FIG. 6A;

FIG. 6C is another example of an access information registration processing ③ of FIG.6A;

FIG. 7A is a flowchart showing a flow of a processing executed in the original disk control unit when the duplexing is resumed
5 from its interruption;

FIG. 7B is a flowchart showing the flow of a processing after the processing ④ of FIG.7A.

DESCRIPTION OF THE PREFERRED EMBODIMENT

10 An embodiment in which the present invention is applied to the duplexed data memory system will be described below.

FIG. 1 of the accompanying drawings is a block diagram showing a duplexed data memory system according to an embodiment of the present invention. As shown in FIG. 1, this duplexed data
15 memory system comprises an original system composed of a main memory unit 1, a original channel unit 2, an original disk control unit 3 serving as an external memory control unit and an original disk unit 4 serving as an external memory unit and a subsystem composed of a main memory unit 5, a subchannel unit 6, a subdisk
20 control unit 7 and a subdisk unit 8 similarly to this original system. The original channel unit 2 and the original disk control unit 3; and the subchannel unit 6 and the subdisk control unit 7 are connected together by interface cables 9 and 10. Also, the original disk control unit 3 and the subdisk control unit 7 are
25 connected by an interface cable 11.

Incidentally, the main memory unit 1 and the original channel unit 2 are connected to a part of a host unit (not shown) or the host unit.

FIG. 2 shows the internal arrangements of the original disk control unit 3 and the subdisk control unit 7.

As shown in FIG. 2, the original disk control unit 3 includes a channel command analyzing section 30, a subdisk control unit command issuing section 31, a subdisk control unit command analyzing section 32, a state management table 33 for managing the state of a duplexing forming disk unit and an access information management table 34 for registering access places of original and sub-disk units obtained during the duplexing is interrupted.

Similarly, the sub-side disk control unit 7 includes a channel command analyzing section 36, an original disk control unit command issuing section 37, an original disk control unit command analyzing section 38, a state management table 39 for memorizing the same information as that of the state management table 33 of the original disk control unit and an access information table 40 for memorizing access places of the subdisk unit obtained during the duplexing is interrupted.

As disk units used as original and sub-disk units, there are generally used magnetic disks, and any disk units may be used so long as they may be used as recording media such as a magnetic tape and a DVD.

FIG. 3 shows contents registered on the state management tables 33, 39 and their abbreviations. A state 1 shows the state in which the duplexed data memory system shown in FIG. 1 is used in the duplexing circumstances and data of the original system and the subsystem are coincident with each other.

A state 2 shows the state in which the duplexed data memory system shown in FIG. 1 is interrupted in use under the duplexing circumstances and data of the original system is updated.

Further, a state 3 shows the state in which the duplexed data memory system shown in FIG. 1 is interrupted in use under the duplexed data circumstances and the write access is made on the subsystem.

The processing operation in the embodiment of the present invention will be described in accordance with the flowcharts of FIGS. 4 to 7. In FIGS. 4 to 7, "state 1", "state 2" and "state 3" shown as the states registered on the state management table are those shown in FIG. 3. The present invention shown in FIGS. 1 to 3 will be described in detail with reference to FIGS. 4 to 7.

FIG. 4A shows a flow of processing executed in the sub-disk control unit 7 until the state management table 39 is set and the access information management table 40 is set since the access occurs in the sub-disk unit 7.

In FIG. 4A, if the command received at the channel command analyzing section 36 of the sub-disk unit 7 is the access to

duplexed data (step 100) and is also the write access (step 110), then the state management table 39 is checked. Then, the state is the duplexing ("state 1") (step 120), then a command of the requested write access is rejected (step 130).

5 If the state is the duplexing interruption ("state 2") (step 140), then the duplexing interruption write access state ("state 3") is registered on the state management table 39 (step 150), and such state is reported to the original disk control unit 3 (step 160) by a dedicated command. Also in the original disk
10 control unit 3, the received state is similarly registered on the state management table 33.

With respect to the registration processing ① of access information on the sub-disk unit 8 in FIG. 4A, as shown in FIG. 4B, write access place information may be registered on the access
15 information management table 40 (step 170). Alternatively, as shown in FIG. 4C, the access information may be reported to the original disk control unit 3 by a dedicated command (step 180).

When the access information registration processing shown in FIG. 4B is realized, after the access to the backup data was
20 ended, the disk control unit for controlling original data collectively reads out update place information of backup data from the disk control unit which controls the backup data.

On the other hand, when the access information registration processing shown in FIG. 4C is realized, after the access to the
25 backup data was ended, the disk control unit for controlling backup

data collectively reports update place information of backup data to the disk control unit which controls original data.

In any cases, the original disk control unit 3 merges received access information to access information relative to the original disk unit 3, and registers merged access information on the access information management table 34.

Then, FIG. 5 shows a flow of a processing executed in the sub-disk control unit 7 until the access information is reported to the original disk control unit 3 since the access to the sub-disk unit 8 was ended.

In FIG. 5A, if a command received at the channel command analyzing section 36 of the sub-disk control unit 7 is an access end command relative to the sub-disk unit 8 which is placed in the duplexed data state (step 300), then the end of the access is reported to the positive disk control unit 3 by a dedicated command from the positive disk control unit command issuing section 37 (step 310).

Then, if the write access of the duplexing interruption is carried out with reference to the state management table 39 (step 320), then a processing ② in which the access information is reported to the original disk control unit 3 is realized by a method of FIG. 5B or FIG. 5C.

When this processing ② is realized by the method shown in FIG. 5B, the access information read request from the original disk control unit 3 is awaited (Step 330). Then, after such

request is received, the access information is reported to the original disk control unit 3 by a dedicated command (step 340), and the contents of the access information management table 40 are cleared (step 350).

5 On the other hand, when the processing ② is realized by the method shown in FIG. 5C, the access information is reported to the original disk control unit 3 by a dedicated command (step 360), and the contents of the access information management table 40 are cleared (step 370). Thereafter, the duplexing interruption
10 information is registered on the state management table 39 (step 380).

FIG. 6 shows a flow of a processing executed by the original disk control unit 3 until the access information of the sub-disk unit 8 is obtained after the access end report to the sub-disk
15 unit 8 was received.

In FIG. 6A, after the access end report was received at the sub-disk control unit command analyzing section 32 of the original disk control unit 3 (step 400), the state management table 33 is checked. If the write access of the duplexing interruption is
20 carried out (step 410), then an access information registration processing ③ may be realized by either method shown in FIG. 6B or FIG. 6C.

If the processing shown in FIG. 6B is executed, then the access information read command is issued to the sub-disk control
25 unit 7 by a dedicated command (step 420), and the read-out

information is merged to the access information relative to the original disk unit 4 and then registered on the access information management table 34 (step 430).

If the processing shown in FIG. 6C is executed, then the report of the access information from the sub-disk control unit 7 is awaited (step 440), and the received information is merged to the access information relative to the original disk unit 4 and then registered on the access information management table 34 (step 450). Thereafter, the sub-side write access information of the duplexing interruption is registered on the state management table 33 (step 460).

Further, FIG. 7 shows a flow of a processing executed in the original disk control unit 3 when the duplexing is resumed from the interruption in the embodiment.

A command in which information indicating whether data of the original disk unit 4 obtained after the duplexing is resumed is used as data of the original disk unit 4 obtained in the duplexing interruption (original data is used) or as data of the sub-disk unit 8 (sub-data is used) is added to a conventional duplexing resume command is prepared as a new duplexing resume command.

In FIG. 7A, if it is determined by the channel command analyzing section 30 of the original disk control unit 3 that the command from the original channel unit 2 is the duplexing resume command (step 600), then the state management table 33 is checked. Then, if such command is placed in other states than the duplexing

interruption state (step 610), then the command is rejected (step 620). If the state is the duplexing interruption state and the added information of the duplexing resume command represents original data use (step 630), then the access information management table 34 is checked, and the write command relative to the access place is issued to the sub-disk unit 8 (step 640). If the added information of the duplexing resume command does not represent the original data use (i.e. represent sub-data use) (step 630), then the access information management table 34 is checked, a read command relative to the access place is issued to the sub-disk control unit 7 (step 680), and the data thus obtained is written in the original disk unit 4 (step 690).

Following the steps 640 and 690, as shown in FIG. 7B, duplexing information is registered on the state management table 33 (step 650), and contents of the access information management table 34 are cleared (step 660). Also in the sub-disk control unit 7, after the writing of received data is ended at the step 640, or when data was reported at the step 680, duplexing information is registered on the state management table 39.

As described above, the sub-disk control unit 7 memorizes information of update place in response to the access to the backup data. After the access was ended, the original disk control unit 3 reads out such information from the sub-disk control unit 7. Alternatively, after the access was ended, the sub-disk control unit 7 reports such information to the original disk control unit

3 so that each time the access occurs in the backup data, the update place obtained by the accessing of the sub-disk unit 8 is reported to the original disk control unit 3.

As described above, according to the multiplexed data memory system of the present invention, under the circumstances comprising the original system for executing the business and the sub-system holding its backup data, resources may be effectively utilized by accessing the read and write from and on the backup data.

Also, the multiplexing of data may be efficiently reorganized by copying only the update place data from the original system disk unit to the sub-system disk unit or copying only the update place data from the sub-system disk unit to the original system disk unit after the access was ended.

Having described a preferred embodiment of the invention with reference to the accompanying drawings, it is to be understood that the invention is not limited to that precise embodiment and that various changes and modifications could be effected therein by one skilled in the art without departing from the spirit or scope of the invention as defined in the appended claims.
